

```
class Control extends React.Component {
  state = { text: '' }

  onClick = _ => window.alert(`Secret: ${this.state.text}`);

  render() {
    return (
      <div>
        <input
          value={this.state.text}
          onChange={e => this.setState({text: e.target.value})}
        />
        <button onClick={this.onClick} type="button">
          Submit
        </button>
      </div>
    )
  }
}
```

**Do I really need a
stateful component?**
